Abstract—After studying literatures mentioned in the literature review chapter, it is understood that there are some gaps in design of shell and tube air preheater. The main aim of the project investigation is to modify the design of air preheater, mentioned in Das et al. [40] to increase its heat transfer coefficient and hence improving its performance and efficiency. The tubular preheater ducts for cold and hot air require more space and structural supports than a rotating preheater design. Further, due to dust-laden abrasive flue gases, the tubes outside the ducting wear out faster on the side facing the gas current. Many advances have been made to eliminate this problem such as the use of ceramic and hardened steel. This project also contains the method for calculating boiler efficiency using indirect method and reduce the losses in air preheater by changing the tube diameter of air preheater in ANSYS Fluent (CFD) software and validating its results from literature Das et al. [40].

Keywords: CFD, ANSYS

I. INTRODUCTION

A primary air heater is a tubular air heater which is arranged in the form of cross-flow heat exchanger. Many primary air heaters are used in coal-fired power plants, steel manufacturing industries, power plant etc. The cross-flow air heater is very popular due to its low cost and easiness of cleaning, operating and maintaining. Normally, the heat exchanger (known as the primary air heater) is recovered heat from the high temperature flue gas to warm up the combustion air to ensure the coal is dried before transporting to the furnace. This heat exchanger is operated under high particulate conditions where fly ash from the combustion process tends to decrease its performance. Unfortunately, there is lack of data about the performance decreasing due to this condition.

For boiler & furnace air is a primary component. In each of this equipment, the ambient air is required to be heated up to high temperatures. Preheating the incoming air largely improves the thermal efficiency of the system, therefore, it increases the energy savings of the industry and as a results lower operating costs. In fact, every 220°C rise in combustion air temperature increases the boiler efficiency by nearly 1%. Heat exchangers can be used to recover the heat from various processes to preheat the air. However, the heat transfer coefficient of air is low and hence, fins or extended surfaces are used to enhance the heat transfer. It is a common industrial practice to utilize the heat of exhaust gases or flue gases and process steam to preheat ambient air. Air pre-heater is the most common equipment responsible for deterioration in boiler efficiency and increase in auxiliary power consumption in ID (Induced draft), FD (Forced draft), and PA (Primary air) fans. [28]

Fig. 1.1: Air Preheater [28]

An air preheater (APH) is a general term used to describe any device designed to heat air before another process (for example, combustion in a boiler) with the primary objective of increasing the thermal efficiency of the process. They may be used alone or to replace a recuperative heat system.

A. Types Of Air Preheater:

There are mainly two types of air preheater on the basis of operating principle.

1) Recuperative Air Preheater:

In such type of air preheater, heat is transferred continuously and directly through stationary, solid heat transfer surface which separate the hot flow steam from cold flow steam. The common heat transfer surfaces are tubes & parallel plates. [30]

a) Tubular Air Preheater:

In such type energy is transferred from the hot flue gas flowing inside thin walled tubes to the cold combustion air flowing outside the tubes. The unit is consist of nest of straight tube that are rolled or welded into tube sheets & enclosed in a steel casing or gas passing outside of the tubes & has both air and gas inlet & outlet openings.
Optimization of Heat Transfer Coefficient of Air Preheater using Computational Fluid Dynamics
(IJSRD/Vol. 4/Issue 05/2016/009)

II. LITERATURE REVIEW

2) Regenerative Air Preheater:
This type is relatively compact and are the most widely used type for combustion air preheating in electric utility steam generating plants. Air to gas leakage can be controlled by cold presenting axial and radial seal plates to minimize gaps at the hot operating condition or using sacrificial material [28].

There are two types of regenerative air preheaters: the rotating-plate regenerative air preheaters (RAPH) and the stationary-plate regenerative air preheaters (Rothenhulke).

In this course we'll consider the motion of single phase fluids, i.e. either liquid or gas, and we'll treat them as continuum. The three primary unknowns that can be obtained by solving these equations are (actually there are five scalar unknowns if we count the three velocity components separately)

- Velocity vector V
- Pressure p
- Temperature T

III. METHODOLOGY

A. Governing Equations of Fluid Flow and Heat Transfer:
Following fundamental laws can be used to derive governing differential equations that are solved in a Computational Fluid Dynamics (CFD) study [1]
- conservation of mass
- conservation of linear momentum (Newton's second law)
- conservation of energy (First law of thermodynamics)

In this course we'll consider the motion of single phase fluids, i.e. either liquid or gas, and we'll treat them as continuum. The three primary unknowns that can be obtained by solving these equations are (actually there are five scalar unknowns if we count the three velocity components separately)

- Velocity vector V
- Pressure p
- Temperature T
But in the governing equations that we solve numerically following four additional variables appear
- Density $\rho$
- Enthalpy $h$ (or internal energy $e$)
- Viscosity $\mu$
- Thermal conductivity $k$

Pressure and temperature can be treated as two independent thermodynamic variables that define the equilibrium state of the fluid. Four additional variables listed above are determined in terms of pressure and temperature using tables, charts or additional equations. However, for many problems it is possible to consider $\rho, \mu$ and $k$ to be constants and to be proportional to with the proportionally constant being the specific heat.

Due to different mathematical characters of governing equations for compressible and incompressible flows, CFD codes are usually written for only one of them. It is not common to find a code that can effectively and accurately work in both compressible and incompressible flow regimes. In the following two sections we'll provide differential forms of the governing equations used to study compressible and incompressible flows.

### B. Heat Exchangers:

Heat Exchangers are classified according to their function and geometry:
- **Function:**
  - Recuperative: two fluids separated by a solid wall
  - Evaporative: enthalpy of evaporation of one fluid is used to heat or cool the other fluid.
  - Regenerative: use a third material which stores/releases heat
- **Geometry:**
  1. Double Tube
  2. Shell and Tube
  3. Cross-flow Heat Exchangers
  4. Compact Heat Exchangers

The heat transfer rate for most heat exchangers can be calculated using the LMTD-method (Log Mean Temperature Difference), if the inlet ($T_1$) and outlet ($T_2$) temperatures are known:

$$Q = U A \Delta T$$

$$\Delta T = \frac{T_2 - T_1}{\ln\left(\frac{T_2}{T_1}\right)}$$

Where, $U$ = Overall heat transfer coefficient [W/m²-°C]

$A$ = Effective heat transfer surface area [m²]

$F$ = Geometry correction factor

$\Delta T$ = Log mean temperature difference

### C. Cross Flow And Compact Heat Exchangers:
- Cross-flow and compact heat exchangers are used where space is limited. These aim to maximize the heat transfer surface area.
- Commonly used in gas (air) heating applications.
- The heat transfer is influenced by whether the fluids are unmixed (i.e. confined in a channel) or mixed (i.e. not confined, hence free to contact several different heat transfer surfaces).
- In a cross-flow heat exchanger the direction of fluids is perpendicular to each other.
- In Compact heat exchangers, the heat transfer rate is directly related to pressure loss

### D. Study Data:
This project work has been focused on the improvement in performance of Air Preheater resulting from by modified the existing design and reduction in various heat losses by changing air preheater parameters. By considering data referred by “Das et al. [40]”, was used indirect method for calculation. So, by taking a reference of this indirect method and analysis of various losses this research has been calculated. [24]

1) Water /Steam Parameters:
- Temperature & pressure measurement of water at economizer inlet and that of steam at boiler outlet.
- Steam flow rate(steam pressure, steam generation per hour)
- DM water quality.
- Feed water analysis.
- Fuel consumption rate per hour, humidity factor etc.
2) Fuel:
- Collection of fuel samples
- Ultimate analysis of the fuel(H2O2,S,C, Moisture content, ash content)
3) Flue Gas/Ash Analysis:
- Collection of ash samples, for unburnt analysis.
- Online readings for flue gas analysis.
- Percentage of oxygen or CO2 in flue gas.
- Flue gas temperature in °C(FGT)

### 4) Surface Condition:
- Measurement of surface temperature.
- Other Data
  - G.C.V of fuel in kcal/kg.
  - Percentage combustible in ash (in case of solid fuel)
  - G.C.V of ash in kcal/kg(in case of solid fuel)
  - Ambient temperature in °C (Ta) and humidity of air in kg/kg of dry air.
- Data from heat recover device(if attach)

5) Experiment Data [40]:

Daily 3 shift wise boiler “log sheet” format.

Modeling And Meshing Of Air Preheater:

Air preheater is modeled by using Creo Parametric 2.0. The Creo Parametric is the one of the most efficient modeling software which can use easily modeling and design the objects. After modeling the design of air preheater which can export this file into Finite volume method software because the modal is done for discretizing or meshing process.

**IV. RESULTS AND DISCUSSIONS**

**A. Simulation Results:**

The governing equations of the problem were solved, numerically, using a control volume method, and finite element volume (FEV) used in order to calculate the thermo physical properties. As a result of a grid independence study, a various grid size founded for different geometry to model accurately the flow fields described in the corresponding results. The accuracy of the computer model was verified by experimental result and improve the performance of air preheater. In present investigation various results, which are shown in table 4.1, 4.2 and 4.3.

Table 4.3: Validation of results from Das et al. [40] and Present ANSYS Fluent result

B. Validation:

In this step all results are validated from Das et al. [40] and Present investigation results and concluded the results.

Fig. 4.1: Contour plot of Static Pressure in Air Preheater (Tube diameter 43.5)  
Figure 4.1 shows the static pressure contour plotting of the air preheater. The pressure at the air inlet is more than at the air outlet.

Fig. 4.2: Contour plot of static Pressure in Air Preheater (cross section) (Tube diameter 43.5)
Figure 4.2 shows the static pressure contour plotting of cross section of the air preheater.

Figure 4.5 shows that the radial velocity contour plotting of the air preheater. The contour shows that the flow of air in duct and tube in radial direction.

Figure 4.3 shows the velocity contour plotting of the air preheater. The contour is shows that the flow of air in duct.

Figure 4.6 shows the contour plotting of wall temperature in the duct and tube walls.

Figure 4.4 shows the axial velocity contours which is calculated by ANSYS Fluent software.

Figure 4.7 shows the skin friction coefficient contour plotting of air preheater. The figure indicates that the skin friction coefficient is very low, hence the generation of wall shear stress is also low for increasing heat transfer rate.

Figure 4.8 shows the graph between flue gas outlet temperature and different tube diameters. It indicates that when the diameter of tube decreases flue gas temperature also reduces.
The figure 4.9 shows the graph between air outlet temperature and different tube diameters. It indicates that when the diameter of tube decreases air outlet temperature increases.

The figure 4.10 shows the graph between flue gas side pressure drop and different tube diameters. It indicates that when the diameter of tube decreases flue pressure drop also reduces. In present investigation the flue gas side pressure drop is 12% less as compare to Das et al. [40].

The figure 4.11 shows the graph between air side pressure drop and different tube diameters. It indicates that when the diameter of tube decreases air side pressure drop is increased. Due to increase in air side pressure drop the performance of air preheater is improved. In present investigation the air side pressure drop is 40% more as compare to Das et al. [40].

Overall conclusion of the present investigation is that diameter of 43.5mm is more efficient for air preheater design than 63.5mm diameter as mentioned in Das et al. [40].

V. CONCLUSION

- In this thesis mainly focused on the of heat transfer coefficient and heat losses, and increase performance of the air preheater.
- Also in this thesis, an alternate design of Air preheater has been proposed by using change of air preheater tube parameter.
- Tube geometry is important design parameters of air preheater modules, since proper selection of tube diameter, thickness, number of tubes in parallel & perpendicular direction etc. results in optimum design of air preheater module.
- It concluded that when the diameter of tube decreases flue pressure drop also reduces. In present investigation the flue gas side pressure drop is 12% less as compare to Das et al. [40].
- It also concluded that when the diameter of tube decreases air side pressure drop is increased. Due to increase in air side pressure drop the performance of air preheater is improved. In present investigation the air side pressure drop is 40% more as compare to Das et al. [40].
- Screen covered many results has been founded to be best option in terms of overall size of the air preheater. It can be clearly seen from result tables that as change tube outside diameter from 63.5 mm to 43.5 mm, there is
saving of 6 to 7% of tube material. Overall size of air preheater is reduced & results in compact design.

- When the diameter of tube decreases heat transfer coefficient is increased. The present investigation shows that the heat transfer coefficient has increased by 9% as compare to Das et al. [40].

- Overall conclusion of the present investigation is that diameter of 43.5mm is more efficient for air preheater design than 63.5mm diameter as mentioned in Das et al. [40].
