Abstract—The power sector is one of the sectors of the India’s economy. The development of the country to a large extent is dependent on the growth of this sector. Through the progress of the power sector during the past four decades has been sustainable, the power industry has been unable to fulfill primary obligation of production quality power supply in required quantity. Our project was mainly concerned with the PowerPlant Operations & efficiency improvement. Initially, we calculated the performance and efficiency of the Boiler. The Computational Fluid Dynamics (CFD) approach is utilized for the creation of a two-dimensional model of the super heater or reheater coil. Using sanicro 25 material in the super heater or reheater part it gives better performance compared with the SA-213material (highly used at present). The fluid flow temperature, pressure is increase and velocity is decrease field of fluid flow within a super heater or reheater tube using the actual boundary conditions have been analyzed using CFD tool.

Key words: CFD, Thermal Power Plant Cycle

I. INTRODUCTION

A thermal power station is a power plant in which heat energy is converted to electric power. In most of the world the turbine is steam driven. Water is heated, turns into steam and spins a steam turbine which drives an electrical generator. After it passes through the turbine, the steam is condensed in a condenser and recycled to where it was heated; this is known as a Rankine cycle. The greatest variation in the design of thermal power stations is due to the different heat sources, fossil fuel dominates here, although nuclear heat energy and solar heat energy are also used. Some prefer to use the term energy centre because such facilities convert forms of heat energy into electrical energy. Certain thermal power plants also are designed to produce heat energy for industrial purposes of district heating, or desalination of water, in addition to generating electrical power. Globally, fossil-fuel power stations produce a large part of man-made CO2 emissions to the atmosphere, and efforts to reduce these are varied and widespread.

Sanicro 25 is an austenitic 22Cr25NiWCoCu stainless steel material with excellent high temperature properties, designed for use in advanced pulverized coal fired steam boilers. The energy efficiency of a conventional thermal power station, considered salable energy produced as a percent of the heating value of the fuel consumed, is typically 33% to 48%. As with all heat engines, their efficiency is limited, and governed by the laws of thermodynamics.

II. WORKING

Thermal power plants use water as working fluid. Nuclear and coal based power plants fall under this category. The way energy from fuel gets transformed into electricity forms the working of a power plant. In a thermal power plant a steam turbine is rotated with help of high pressure and high temperature steam and this rotation is transferred to a generator to produce electricity. When turbine blades get rotated by high pressure high temperature steam, the steam loses its energy. This in turn will result in a low pressure and low temperature steam at the outlet of the turbine. Here steam is expanded till saturation point is reached. Since there is no heat addition or removal from the steam, ideally entropy of the steam remains same. This change is depicted in the following p-v and T-s diagrams. If we can bring this low pressure, low temperature steam back to its original state, then we can produce electricity continuously. Compressing a fluid which is in gaseous state requires a huge amount of energy, so before compressing the fluid it should be converted into liquid state. A condenser is used for this purpose, which rejects heat to the surrounding and converts steam into liquid. Ideally there will not be any pressure change during this heat rejection process, since the fluid is free to expand in a condenser. Changes in fluid are shown in the p-v and T-s diagram below. At exit of the condenser fluid is in liquid state, so we can use a pump to raise the pressure. During this process the volume and temperature (2-3 °C rise) of fluid hardly changes, since it is
in liquid state. Now the fluid has regained its original pressure.

Here external heat is added to the fluid in order to bring fluid back to its original temperature. This heat is added through a heat exchanger called a boiler. Here the pressure of the fluid remains the same, since it is free to expand in heat exchanger tubes. Temperature rises and liquid gets transformed to vapor and regains its original temperature. This completes the thermodynamic cycle of a thermal power plant, called Rankine Cycle. This cycle can be repeated and continuous power production is possible. In order to reject heat from the condenser a colder liquid should make contact with it. In a thermal power plant continuous supply of cold liquid is produced with the help of a cooling tower. Cold fluid from the cooling tower absorbs heat from a condenser and gets heated, this heat is rejected to the atmosphere via natural convection with the help of a cooling tower.

Heat is added to the boiler with help of a boiler furnace. Here fuel reacts with air and produces heat. In a thermal power plant, the fuel can be either coal or nuclear. When coal is used as a fuel it produces a lot of pollutants which have to be removed before ejecting to the surroundings. This is done using a series of steps, the most important of them is an electro static precipitator (ESP) which removes ash particles from the exhaust. Now much cleaner exhaust is ejected into the atmosphere via a stack.

III. APPROACH TO INCREASE THE EFFICIENCY OF THE RANKINE CYCLE

The efficiency of Rankine cycle can be improved with considering following points:

A. Lowering the Condenser Pressure

Inside the condenser steam exists as a saturated mixture at the saturation temperature corresponding to the pressure inside the condenser. Therefore, lowering the operating pressure of the condenser automatically lowers the temperature of the steam. It increases the turbine output. It cannot be lower than the temperature of the cooling medium. Because, it increases the moisture content of the steam at the final stages of the turbine and it erodes the turbine blades. Finely decreases the turbine efficiency. Luckily, this problem can be solved by reheating of steam.

B. Superheating the Steam to High Temperatures

Superheat the steam to very high temperatures before it enters the turbine. This would be the desirable solution since the average temperature at which heat is added would also increase, thus increasing the cycle efficiency. However, it has the limitation to rise the steam temperature up to metallurgically safe levels. A super heater is used in this process.

IV. Super heater

Super heater tubes are surfaces for heat exchange, with the object of increasing the steam temperature, after it comes from the boiler drum, to a value higher than saturation. This has two basic purposes: to increase the thermodynamic efficiency of the turbine, in which the steam will be expanded and to make the steam free of humidity. In normal operation it produces steam that is superheated by approximately 200 °C at the inlet of the turbine. The steam flow has to be intense to permit the heat absorption from the tube, avoiding deformation because of high temperature. The super heater can be divided in two sections, primary and secondary, as in the boiler studied, where the super heater tubes are within the radiation zone.

V. METHODOLOGY

A. We have considered an example to illustrate the change of efficiency with change in temperature

A boiler plant incorporates an economizer and super heater and generates steam at 40 bar and 300 °C with fuel heating value 33,000 KJ/kg burned at a rate of 50 kg/h. The temperature of feed water is raised from 40 °C to 125 °C in the economizer and the flue gases are cooled at the same time from 395 °C to 225 °C. The flue gases then enter the super heater in which the temperature of combustion air is raised by 75 °C. A forced draught fan delivers the air to the super heater at a pressure of 1.02 bar and a temperature of 16 °C with a pressure rise across the fan of 180 mm of water. The power input to the fan is 5 kW and it has a mechanical efficiency of 78%. Neglecting heat losses and taking Cg as 1.01 KJ/kg K for flue gases, Calculate:

- The mass flow rate of air,
- The temperature of flue gases leaving the plant,
- The mass flow rate of steam
- The efficiency of the boiler

1) Solution:

Power output to the FD fan,

\[ P = \eta_{mech} \cdot V \]

\[ \eta_{mech} = \frac{\rho_a \cdot V}{\rho_a \cdot V + \Delta h} \]

\[ \frac{\rho_a \cdot V}{\rho_a \cdot V + \Delta h} = \frac{3100 \cdot 9.81 \cdot 0.180}{1000 \cdot 6.78} = 2.21 \text{ m}^3/\text{s} \]

Density of air, \( \rho_a = \frac{P}{R \cdot T} \)

\[ \rho_a = \frac{1.02 \cdot 10^5}{287 \cdot (273 + 16)} = 1.23 \text{ kg/s} \]

Mass flow rate of air, \( m_a = \rho_a \cdot V \)

\[ m_a = 1.23 \cdot 2.21 \]

\[ = 2.27 \text{ kg/s} \]

- Assuming complete combustion of fuel, the mass flow rate of flue gases,

\[ m_f = m_a + m_t \]

\[ = 2.72 + \frac{500}{3600} \]

\[ = 2.855 \text{ kg/s} \]

Energy lost by flue gas = energy gained by air in super heater

\[ 2.855 \cdot 1.01 \cdot \Delta T = 2.72 + 1.005 \cdot 75 \]

\[ \Delta T = \text{temperature drop of the flue gases} = 71 ^\circ C \]

Temperature of flue gases leaving the plant, \( 225 - 71 = 154 ^\circ C \)

Making energy balance for he economizer,

\[ m_a \cdot c_w \cdot (125 - 40) = m_f \cdot c_{fg} \cdot (395 - 225) \]

\[ m_a = \frac{2.2855 \cdot 1.01 + 170}{4.182 + 85} = 1.379 \text{ kg/s} \]

Water enters the boiler as feed water at 40 °C

\[ h_l = 167.4 \text{ KJ/kg} \]

Steam leaves the boiler at 40 bar, 300 °C

\[ h = 2962.3 \text{ KJ/kg} \]

Boiler efficiency = \( \frac{2962.3 - 167.4}{33000 \cdot \frac{300}{5600}} \)

\[ = 0.84 \text{ or } 84\% \]

Now if we change the temperature leaving the super heater or boiler, from 300 °C to 350 °C, then the Steam leaves the boiler at 40 bar, 350 °C

\[ h = 3090.94 \text{ KJ/kg} \]

Boiler efficiency = \( \frac{3090.94 - 167.4}{33000 \cdot \frac{300}{5600}} \)

\[ = 0.8796 \text{ or } 88\% \]

From the illustration we can see that the small change in temperature leaving the super heater or boiler results in respective changes in boiler efficiency

B. Material considered in the project

Presently in India, SA-213 Gr.22 metal is being widely used for the production of super heaters. These kind of super heaters can only withstand temperatures up to 500 °C only. So we have considered a metal that can withstand temperatures up to 700°C and is being used for super heaters in few parts of the world

SANICRO 25-Sanicro 25 is an austenitic 22Cr25NiWCoCu stainless steel material with excellent high temperature properties, designed for use in advanced pulverized coal fired steam boilers. The grade is characterized by:

- Very – high creep strength
- High oxidation resistance
- High structural stability
- Good fabricability

Table 3: Max allowable stress values

The weldability of Sanicro 25 is also good and TIG welding method is recommended, and should be carried out with a low heat input, <1.0kJ/mm and an interpass temperature <100°C. The material has been specifically developed for use at material temperature upto around 700°C.

VI. ANALYSIS OF SUPER HEATER

In order to perform a CFD analysis, a powerful tool like ANSYS is widely used presently. ANSYS Fluent, CFD, CFX, and related software are Computational Fluid Dynamics software tools used by engineers for design and analysis. These tools can simulate fluid flows in a virtual environment, for example gas turbine engines (including the compressors, combustion chamber, turbines and afterburners), pumps.

A. Creating the 3D Model

To create the 3d model of the super heater, CATIA V5 a cad based designing product was used. Then its been imported to the ANSYS 14.5 for further CFD analysis of the 3d model.

B. Meshing the 3D Model

After importing the 3d model in the ANSYS workbench, the model is meshed with high smoothing and fine coursing. The sections like inlet, outlet, outer surface and inner surface of the tube are projected or named for the CFD analysis.

VII. RESULTS

Considering the boundary conditions for a super heater tube, air is used as the fluid in the tube. CFD analysis has been carried out assuming the optimum surface conditions for the tube.

VIII. CONCLUSION

Increased efficiency in coal-fired power plant Our new material Sanicro 25 is engineered for the next generation of coal-fired power boilers, contributing to significantly greater efficiency and sharply lower CO2 emissions. It is ideal for superheater and reheater tubes, allowing for material temperatures of up to 700°C (1290°F).

As per results obtained from the CFD analysis it is seen that the new material considered has low stress levels and high thermal values. The material has high strength, very good resistance to hot corrosion, very high oxidation resistance in a coal ash environment. The weldability of Sanicro 25 is also good and TIG welding method is recommended.
